## Pset 4 - Due: Wednesday, October 2

1. Convert the following ER diagram, which models the operational data for a department store, to a set of relations that conform to Third Normal Form (3NF)

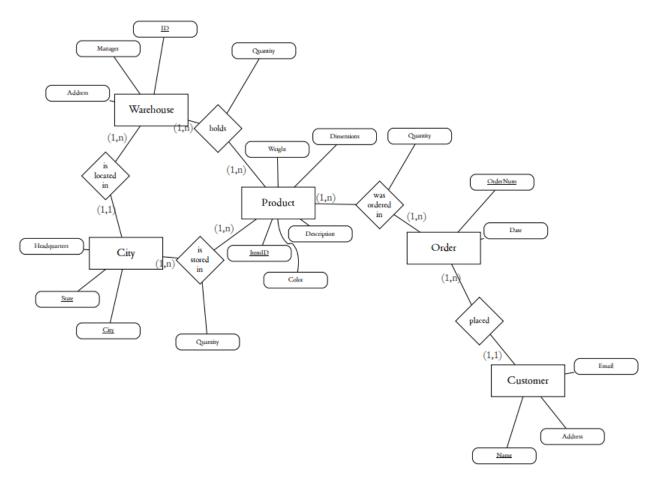

Figure 1: Entity relationship diagram

1.) First, we convert the strong, non-subtype entities to relations. We have

Warehouse(<u>ID</u>, Address, Manager)
City(<u>State</u>, <u>City</u>, Headquarters)
Product(<u>ItemID</u>, Color, Description, Weight, Dimensions)
Order(<u>OrderNum</u>, Date)
Customer(Name, Address, Email).

Since there are no subtype or weak entities, we move to the relationships. There are 5 relationships, two binary one-to-many, and 3 binary many-to-many. We start with the simpler.

To handle the binary one-to-many relationships, we insert a foreign key in the many entity to the one entity. Thus,

Warehouse(<u>ID</u>, Address, Manager, City<sup>†</sup>) City(<u>State</u>, <u>City</u>, Headquarters) Order(<u>OrderNum</u>, Date, Name<sup>†</sup>) Customer(<u>Name</u>, Address, Email).

Where city in the warehouse relation is a foreign key to the city relation, and name in the order relation is a foreign key to the customer relation. The implied functional dependencies are

$$\begin{split} & \text{ID} \rightarrow \text{City} \\ & \text{OrderNum} \rightarrow \text{Name}. \end{split}$$

Next, we need to handle the remaining relationships, which are the three binary many-to-many. For these, we create a new relation. The primary key of the new relations will be the concatenation of the primary keys of the entity relations, and the intersection data as non-prime attributes

Warehouse(<u>ID</u>, Address, Manager, City<sup>†</sup>)
City(<u>State</u>, <u>City</u>, Headquarters)
Product(<u>ItemID</u>, Color, Description, Weight, Dimensions)
Order(<u>OrderNum</u>, Date, Name<sup>†</sup>)
Customer(<u>Name</u>, Address, Email)
ProductHolding(<u>ID</u><sup>†</sup>, <u>ItemID</u><sup>†</sup>, quantity)
ProductStoredIn(<u>City</u><sup>†</sup>, <u>ItemID</u><sup>†</sup>, Quantity)

The Product Holding relation has a foreign key ID to the Warehouse relation, and for eign key ItemID to the Product relation.

ProductOrderedIn( $\underline{\text{ItemID}}^{\dagger}$ ,  $\underline{\text{OrderNum}}^{\dagger}$ , Quantity).

The ProductStoredIn relation has a foreign key City to the City relation, and a foreign key ItemID to the Product relation.

The ProductOrderedIn relation has a foreign key *ItemID* to the Product relation, and a foreign key *OrderNum* too the Order relation.

Thus, the final schema of the database is the following eight relations

Warehouse(<u>ID</u>, Address, Manager, City<sup>†</sup>)

City(State, City, Headquarters)

Product(<u>ItemID</u>, Color, Description, Weight, Dimensions)

Order(<u>OrderNum</u>, Date, Name<sup>†</sup>)

Customer(Name, Address, Email)

 $ProductHolding(\underline{ID}^{\dagger},\,\underline{ItemID}^{\dagger},\,quantity)$ 

 $ProductStoredIn(City^{\dagger},\,\underline{ItemID}^{\dagger},\,Quantity)$ 

 $ProductOrderedIn(\underline{ItemID}^{\dagger}, \underline{OrderNum}^{\dagger}, \underline{Quantity}).$
